Part I

A Introduction to Python

This is part of the Python lecture given by Christophe Morisset at IA-UNAM. More informations at: <http://python-astro.blogspot.mx/>

0.1 Using Python as a calculator

Using of “print” command is not necessary to obtain a result. Just type some operations and the result is obtain with ENTER.

```
2 + 22
```

```
In [63]:
```

```
Out [63]: 24
```

```
(2+3) * (3+4) / (5*5)
```

```
In [2]:
```

```
Out [2]: 1
```

Python likes the use of spaces to make scripts more readable

```
(2+3) * (3+4.) / (5*5)
```

```
In [3]:  
Out [3]: 1.4
```

The art of writing good python code is described in the following document:
<http://legacy.python.org/dev/peps/pep-0008/>

0.2 Assignments

Like any other language, you can assign a value to a variable. This is done with = symbol:

```
a = 4
```

In [4]:
A lot of operations can be performed on the variables. The most basics are for example:

```
a
```

```
In [5]:  
Out [5]: 4  
a = a + 1  
a
```

```
In [6]:  
Out [6]: 5  
a *= 4 # Multiply the left argument by the right value  
a
```

```
In [7]:  
Out [7]: 20  
a, b = 1, 2  
a, b
```

```
In [8]:
```

```
Out [8]: (1, 2)
```

Some variable name are not available, they are reserved to python itself: and, as, assert, break, class, continue, def, del, elif, else, except, exec, finally, for, from, global, if, import, in, is, lambda, not, or, pass, print, raise, return, try, while, with, yield

0.3 Comments

```
a = 2 # this is a comment
""" This is a large comment
on multiple lines
ending as it started
"""
```

```
Out [10]: ' This is a large comment\nnon multiple l
```

0.4 Types

The types used in Python are: integers, long integers, floats (double prec.), complexes, strings, booleans.

```
2
In [11]:
Out [11]: 2
2 / 3 # Take care, this will result in an integer, may not be what you expect. This ch

In [12]:
Out [12]: 0
2. / 3 # This is the way exact division is performed, adding a dot to promote one of t

In [13]:
```

```
Out [13]: 0.6666666666666666
```

Double precision: machine dependent, generally between 10^{-308} and 10^{308} , with 16 significant digits. The function `type` gives the type of its argument:

```
type(2)
```

```
In [14]:
```

```
Out [14]: int
```

```
type(2.3)
```

```
In [15]:
```

```
Out [15]: float
```

```
int(0.8) # truncating
```

```
In [16]:
```

```
Out [16]: 0
```

```
round(0.8765566777) # nearest, result is float
```

```
In [17]:
```

```
Out [17]: 1.0
```

```
int(round(0.88766)) # nearest, with the result being an integer:
```

```
In [18]:
```

```
Out [18]: 1
```

0.5 Complex numbers

```
a = 1.5 + 0.5j
```

```
In [19]:
```

```
a**2.
```

```
In [20]:
```

```
Out [20]: (2+1.5j)
```

```
(1+2j)*(1-2j)
```

```
In [21]:
```

```
Out [21]: (5+0j)
```

```
a.real
```

```
In [22]:
```

```
Out [22]: 1.5
```

```
(a**3).imag
```

```
In [23]:
```

```
Out [23]: 3.25
```

```
a.conjugate() # this is a function, it requires ()
```

```
In [24]:
```

```
Out [24]: (1.5-0.5j)
```

0.6 Booleans

Comparison operators are <, >, <=, >=, ==, !=

```
5 < 7
```

```
In [25]:
```

```
Out [25]: True
```

```
a = 5  
b = 7
```

```
In [26]:
```

```
b < a
```

```
In [27]:
```

```
Out [27]: False
```

```
c = 2
```

```
In [28]:
```

```
c < a < b
```

```
In [29]:
```

```
Out [29]: True
```

```
a < b and b < c
```

```
In [30]:
```

```
Out [30]: False
```

```
res = a < 7  
print(res, type(res))
```

```
In [31]: (True, <type 'bool'>)
```

```
print int(res)  
print int(not res)
```

```
In [32]:
```

```
1
```

```
0
```

```
res is True
```

```
In [33]:
```

```
Out [33]: True
```

0.7 Formating strings

```
print "Hello world!"
```

```
In [34]: Hello world!
```

```
print 'Hello world!'
```

```
In [35]: Hello world!
```

```
print "Hello I'm here" # ' inside ""
```

```
In [36]: Hello I'm here
```

```
print('Hello') # this is the Python 3 style
```

```
In [37]: Hello
```

```
# This is the old fashion way of formating outputs (C-style)
```

```
a = 7.5
```

```
b = 'tralala'
```

```
c = 8.9e-33
```

```
In [38]:
```

```
print('a = %f, b = %s, c = %e' % (a, b, c))
```

```
a = 7.500000, b = tralala, c = 8.900000e-33
```

```
# The new way is using the format() method of the string object, and {} to define which
```

```
print('a = {}, b = {}, c = {}'.format(a,b,c))
```

```
print('a = {0}, b = {1}, c = {2}'.format(a,b,c))
```

```
In [39]:
```

```
print('a = {:.f}, b = {:20s}, c = {:.10.3e}'.format(a,b,c))
```

```
a = 7.5, b = tralala, c = 8.9e-33
```

```
a = 7.5, b = tralala, c = 8.9e-33
```

```
a = 7.500000, b = tralala
```

Much more on this here: <https://docs.python.org/2/tutorial/inputoutput.html>

0.8 Strings

```
a = "this is a string"
In [40]: len(a)
```

```
In [41]:
Out [41]: 16
```

A lot of commands can operate on strings. Strings, like ANYTHING in python, are objects. Methods are run on objects by dots:

```
a.upper()
In [42]:
Out [42]: 'THIS IS A STRING'
a.title()
```

```
In [43]:
Out [43]: 'This Is A String'
a.split()
```

```
In [44]:
Out [44]: ['this', 'is', 'a', 'string']
a.split()[1]
```

```
In [45]:
Out [45]: 'is'
```

```
a = "This is a string.    With various sentences."
In [46]: a.split('.') # Here we define the character used to split. The default is space (any c
```

```
In [47]:
Out [47]: ['This is a string', '    With various se
```

```
a = 'tra'
b = 'la'
In [48]: print ' '.join((a,b,b))
print '-'.join((a,b,b))
print ''.join((a,b,b))
```

```
tra la la
tra-la-la
tralala
```

0.9 Containers: Tuples, Lists and Dictionaries

list: a collection of objects. May be of different types. It has an order.

```
L = ['red', 'green', 'blue'] # squared brackets are used to define lists
In [49]: type(L) # Print the type of L
Out [50]: list
L[1]

In [51]:
Out [51]: 'green'

L[0] # indexes start at 0 !!!

In [52]:
Out [52]: 'red'

L[-1] # last element

In [53]:
Out [53]: 'blue'

L[-3]

In [54]:
Out [54]: 'red'

L = L + ['black', 'white'] # addition symbol is used to agregate values to a list. See
In [55]: print L
In [56]: ['red', 'green', 'blue', 'black', 'white']
L[1:3] # L[start:stop] : elements if index i, where start <= i < stop !! stop not incl

In [57]:
Out [57]: ['green', 'blue']

L[2:] # boudaries can be omitted

In [58]:
Out [58]: ['blue', 'black', 'white']
```

```
L[-2:]
```

```
In [59]:
```

```
Out [59]: ['black', 'white']
```

```
L[::2] # L[start:stop:step] every 2 elements
```

```
In [60]:
```

```
Out [60]: ['red', 'blue', 'white']
```

Lists are mutable: their content can be modified.

```
L[2] = 'yellow'  
L
```

```
In [61]:
```

```
Out [61]: ['red', 'green', 'yellow', 'black', 'white']
```

```
L.append('pink') # agregarte a value at the end
```

```
L
```

```
In [62]:
```

```
Out [62]: ['red', 'green', 'yellow', 'black', 'white']
```

```
L.insert(2, 'blue') #L.insert(index, object) -- insert object before index
```

```
L
```

```
In [63]:
```

```
Out [63]: ['red', 'green', 'blue', 'yellow', 'black']
```

```
L.extend(['magenta', 'purple'])
```

```
L
```

```
In [64]:
```

```
Out [64]: ['red',  
           'green',  
           'blue',  
           'yellow',  
           'black',  
           'white',  
           'pink',  
           'magenta',  
           'purple']
```

```
L = L[::-1] # reverse order
L
```

In [65]:

```
Out [65]: ['purple',
           'magenta',
           'pink',
           'white',
           'black',
           'yellow',
           'blue',
           'green',
           'red']
```

```
L2 = L[:-3] # cutting the last 3 elements
```

```
print L
print L2
```

In [66]:

```
['purple', 'magenta', 'pink', 'white', '
'green', 'red']
['purple', 'magenta', 'pink', 'white', '

```

```
L[25] # Out of range leads to error
```

In [67]:

```

L
In []: a = [1,2,3]
b = [10,20,30]

In []: print (a+b) # may not be what you expected, but rather logical too

In []: print (a*b) # Does NOT multiply element by element. Numpy will do this job.
L = range(4) # Create a list. Notice the parameter is the number of elements, not the
In []: L
L = range(0, 20, 2) # every 2 integer
In []: L
```

In []:

The types of the elements of a list are not always the same:

```
L = [1, '1', 1.4]
L
```

In []:

Remove the n+1-th element:

```
L = range(0,20,2)
print L
del L[5]
print L
In []:
```

Slicing: extracting sub-list of a list

```
a = [[1, 2, 3], [20, 20, 30], [100, 200, 300]] # Not a 2D table, but rather a table of
print (a)
print (a[0])
In []: print (a[1][1])

print (a[1,1]) # Does NOT work
b = a[1]
In []: print b
b[1] = 999
In []: print b

In []:
```

```
print a # Changing b changed a !!!
```

```
In []: b[1] is a[1][1]
```

```
In []:
```

tuples: like lists, but immutable

```
T = (1,2,3)
T
```

```
In [68]:
```

```
Out [68]: (1, 2, 3)
```

```
T2 = 1, 2, 3
```

```
print T2
type(T2)
```

```
In [69]:
```

```
(1, 2, 3)
```

```
Out [69]: tuple
```

```
T[1]
```

```
In [70]:
```

```
Out [70]: 2
```

tuples are unmutables

```
T[1] = 3 # Does NOT work!
```

```
In [71]:
```

```
-----
-----

call last)
```

```
<ipython-input-71-6dd68cc28786> in <
----> 1 T[1] = 3 # Does NOT work!
```

TypeError: 'tuple' object does not s

Dictionnaires

A dictionary is basically an efficient table that maps keys to values. It is an unordered container

```
D = {'Christophe': 12, 'Antonio': 15} # defined by {key : value}
In [72]: D['Christophe'] # access to a value by the key
In [73]:
Out [73]: 12

D.keys() # list of the dictionary keys

In [74]:
Out [74]: ['Christophe', 'Antonio']

D['Julio'] = 16 # adding a new entry

In [75]: print D
In [76]: {'Julio': 16, 'Christophe': 12, 'Antonio': 15}

print sorted((1,'t',2,4,5,2,3, 'a', 'b','g','e', 'A', 'G',1.2))

In [77]: [1, 1.2, 2, 2, 3, 4, 5, 'A', 'G', 'a', 'b', 'e', 'g', 't']
T = ('a', 'j', 'D', 'i')
print sorted(T, key = str.upper)

In [78]: ['a', 'D', 'i', 'j']
```

0.10 Blocks

Blocks are defined by indentation. Looks nice and no needs for end :-)

```
for i in [1,2,3]: print(i) # compact way, not recommended.
```

In [79]:

1

2

3

```
for cosa in [1,'ff',2]:
```

```
    print(cosa)
```

```
    print('end')
```

In [80]:

```
print('final end') # end of the indentation means end of the block
```

1

end

ff

end

2

end

final end

```
# defining a dictionary:
```

```
ATOMIC_MASS = {}
```

```
ATOMIC_MASS['H'] = 1
```

```
ATOMIC_MASS['He'] = 4
```

```
ATOMIC_MASS['C'] = 12
```

```
ATOMIC_MASS['N'] = 14
```

```
ATOMIC_MASS['O'] = 16
```

```
ATOMIC_MASS['Ne'] = 20
```

```
ATOMIC_MASS['Ar'] = 40
```

```
ATOMIC_MASS['S'] = 32
```

```
ATOMIC_MASS['Si'] = 28
```

```
ATOMIC_MASS['Fe'] = 55.8
```

```
# Print the keys and values from the dictionary. As it is not ordered, they come as follows
```

In [81]:

```
for key in ATOMIC_MASS.keys():  
    print key, ATOMIC_MASS[key]
```

C 12

H 1

Si 28

Ne 20

O 16

N 14

S 32

Ar 40

Fe 55.8

```
for key in sorted(ATOMIC_MASS): # sorting using the keys
    print('Element: {0:3s} Atomic Mass: {1}'.format(key, ATOMIC_MASS[key]))
```

```
In [82]: Element: Ar      Atomic Mass: 40
         Element: C       Atomic Mass: 12
         Element: Fe      Atomic Mass: 55.8
         Element: H       Atomic Mass: 1

```

In [73]: 0.0

Lambda function is used to creat simple (single line) functions:

```
J = lambda x, y, z: (x**2 + y**2 + z**2)**0.5
J(1,2,3)
```

In [40]:

Out [40]: 3.7416573867739413

```
print((lambda x,y,z: x+y+z)(0,1,2))
```

In [75]: 3

Changing the value of variable inside a routine

Parameters to functions are references to objects, which are passed by value. When you pass a variable to a function, python passes the reference to the object to which the variable refers (the value). Not the variable itself. If the value is immutable, the function does not modify the caller's variable. If the value is mutable, the function may modify the caller's variable in-place, if a mutation of the variable is done (not if a new mutable value is assigned):

```
In [76]: def try_to_modify(x, y, z):
          x = 23
          y.append(22)
          z = [29] # new reference
          print('    IN THE ROUTINE')
          print(x)
          print(y)
          print(z)

          # The values of a, b and c are set
          a = 77

0.14 Importing libraries

Not all the power of python is available when we call (i)python. Some additional librairies (included in the python package, or as additional packages, like numpy) can be imported to increase to capacities of python. This is the case of the math library:

```
print sin(3.)
```

```
In [1]:
```

```
-----  
-----  
NameError  
call last)
```

```
<ipython-input-1-08710d8e7a42> in <n  
----> 1 print sin(3.)
```

```
NameError: name 'sin' is not defined
```

```
import math
print math.sin(3.)
```

In [2]: 0.14112000806

```
math?
```

We can import all the elements of the library in the current domain name (NOT A GOOD

In [4]: **from** math **import** *
sin(3.)

In [5]:

Out [5]: 0.1411200080598672

One can look at the contents of a library with dir:

```
print(dir(math))
```

In [59]: ['__doc__', '__file__', '__name__', '__p
'asin', 'asinh', 'atan', 'atan2', 'atanh
'cosh', 'degrees', 'e', 'erf', 'erfc', '
'factorial', 'floor', 'fmod', 'frexp', '
'isinf', 'isnan', 'ldexp', 'lgamma', 'lo
'pi', 'pow', 'radians', 'sin', 'sinh', '
The help command is used to have information on a given function:
help(math.sin)

In [6]: Help on built-in function sin in module

```
sin(...)  
    sin(x)
```

Return the sine of x (measured in ra

```
help(log)
```

In [7]: Help on built-in function log in module

```
log(...)  
    log(x[, base])
```

Return the logarithm of x to the giv

If the base not specified, returns t
of x.

```
print math.pi
```

```
In [8]: 3.14159265359
```

```
math.pi = 2.71
```

```
In [11]: print math.pi
```

```
In [12]: 2.71
```

```
import math
```

```
In [13]: math.pi
```

```
In [14]:
```

```
Out [14]: 2.71
```

```
reload(math)
```

```
In [15]:
```

```
Out [15]: <module 'math' from '/home/puma/Ureka/va
